## Problems with *Server farms and Caching proxies*

- Server farms do nothing about problems due to network congestion, or to improve latency issues due to the network
- Caching proxies serve only their local clients, not all users on the Internet
- Content providers (say, *Web servers*) cannot rely on *existence* and *correct* implementation of caching proxies
- Accounting issues with caching proxies.  
For instance, *www.cnn.com* needs to know the number of hits to the webpage for advertisements displayed on the webpage

## CDNs

26

## Motivation

29

- IP based networks
- Web based applications have become the norm for corporate internal networks and many business-to-business interactions
- Large acceptance and explosive growth
  - Serious performance problems
  - Degraded user experience

For a large set of applications, including VIDEO access
- Improving the performance of networked applications
  - Handle highly dynamic pages or constant updates.
  - Use many sites at different points within the network
    - Stand alone servers
    - Routers

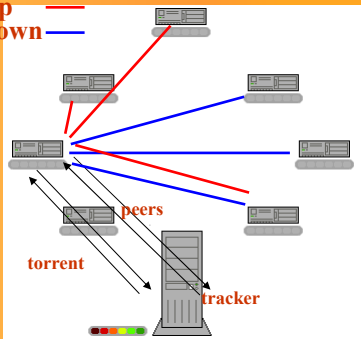

29

## Peer-to-Peer?

30

- BitTorrent has peaked at ~30% Internet BW

1. Download a "torrent" file
2. Contact the tracker
3. Enter the "swarm" network
4. Chunk exchange policy
  - Rarest chunk first or random
  - Tit-for-tat: incentive to upload
  - Optimistic unchoking
5. Validate the checksums

Benefit: extremely good use of resources!

30

31

## Could we use Peer-to-Peer to address the content explosion?

P2P has multiple problems:

- × **Requires custom software**
  - Deployment is a must
  - Configurations needed
- × **Companies usually may want managed service**
  - Handles flash crowds
  - Handles long-lived objects
- × **Brings performance problem**
  - Hard to guarantee the service quality
  - Delay in updating the content

31

## CDNs basics

- **What is a CDN?**
  - A network of servers delivering content on behalf of an origin site
    - A number of CDN companies well established now
      - E.g. Akamai, Digital Island, Speedera, CDN77, Cloudflare, Stackpat
    - Many companies are exploring CDNs
      - Avoid congested portions of the Internet
- **Consist of**
  - Edge servers deployed at several ISP (Internet Service Provider) access locations and network exchange points
- **Large-file service with no custom client, no custom server, no prepositioning**
- **Improve the response time of an Internet site**
  - Offloading the delivery of bandwidth-intensive objects, such as images and video clips
- **Intelligent Internet infrastructure that improves the performance and scalability of distributed applications by moving the bulk of their *computation* to servers located at the edge of the network**
  - Applications are logically split into two components (*after 2<sup>nd</sup> generation*)
    - Executed at an edge server close to the user
    - Executed on a traditional application server

32

33

## CDN Generations

- **First generation (early 90ies): static caching**
  - Accelerate the performance of web sites
  - Support increasing volumes of traffic
    - Key disruption event: 9/11
    - Akamai technologies created
- **Second generation (early 2000ies): dynamic content**
  - Support high volumes of multimedia traffic
  - Audio/video intensive networks
    - All ISPs developed/used CDNs
- **Third generation (2010ies): cloud integration, SDN CDNs**
  - Cloud computing
    - Amazon cloud (2008)
  - UGC (user generated content)
  - P2P and interactivity
    - AT&T distributed data centers (2011)
  - Mobile support, and device adapted content
- **Fourth generation (2020+ still ongoing): edge and federation**
  - Integrates with mobile environments
  - Edge devices (e.g. MEC concepts)
  - Multioperator federation

33

34

## Early Motivations for Content Networks (1<sup>st</sup> generation)

- More hops between client and Web server => more congestion!
- Same data flowing repeatedly over links between clients and Web server
- Origin server is bottleneck as number of users grows
- Flash Crowds (*for instance, Sept. 11*)
  - *The Content Distribution Problem:* Arrange a rendezvous between a content source at the origin server (*www...com*) and a content sink (*users*)

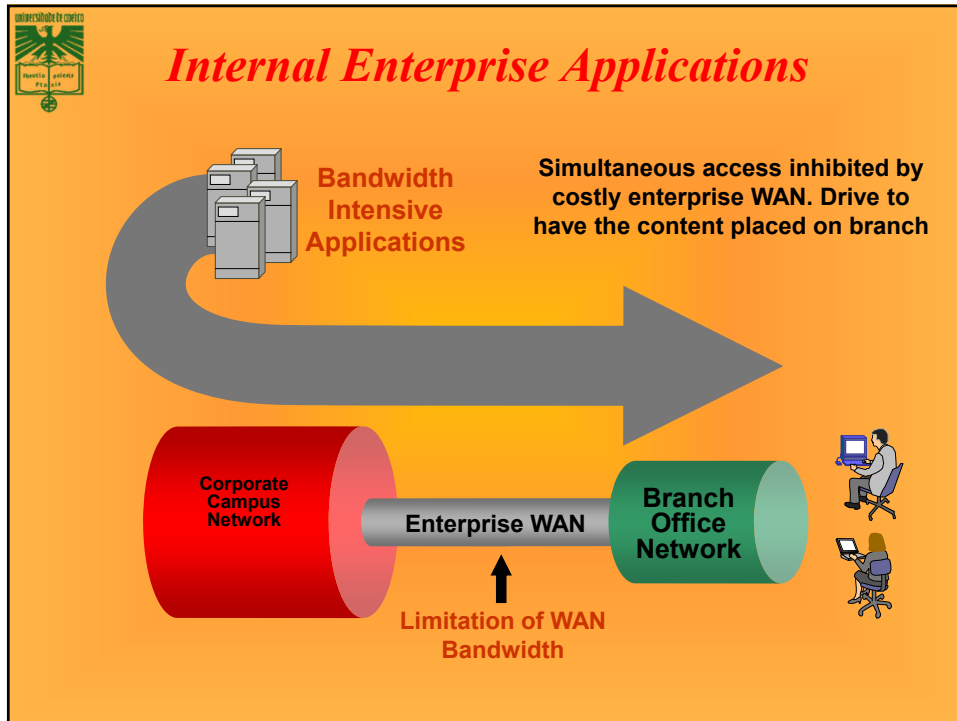

```

graph LR
    S((S)) -- red --> R1(( ))
    R1 -- red --> R2(( ))
    R2 -- red --> R3(( ))
    R3 -- red --> C4((C4))
    R1 -- black --> C1((C1))
    R2 -- red --> C3((C3))
    R3 -- green --> C2((C2))
    style R1 fill:none,stroke:none
    style R2 fill:none,stroke:none
    style R3 fill:none,stroke:none
    style C1 fill:#ccc,stroke:#333
    style C2 fill:#ccc,stroke:#333
    style C3 fill:#ccc,stroke:#333
    style C4 fill:#ccc,stroke:#333
    style S fill:#0000ff,color:#fff
  
```

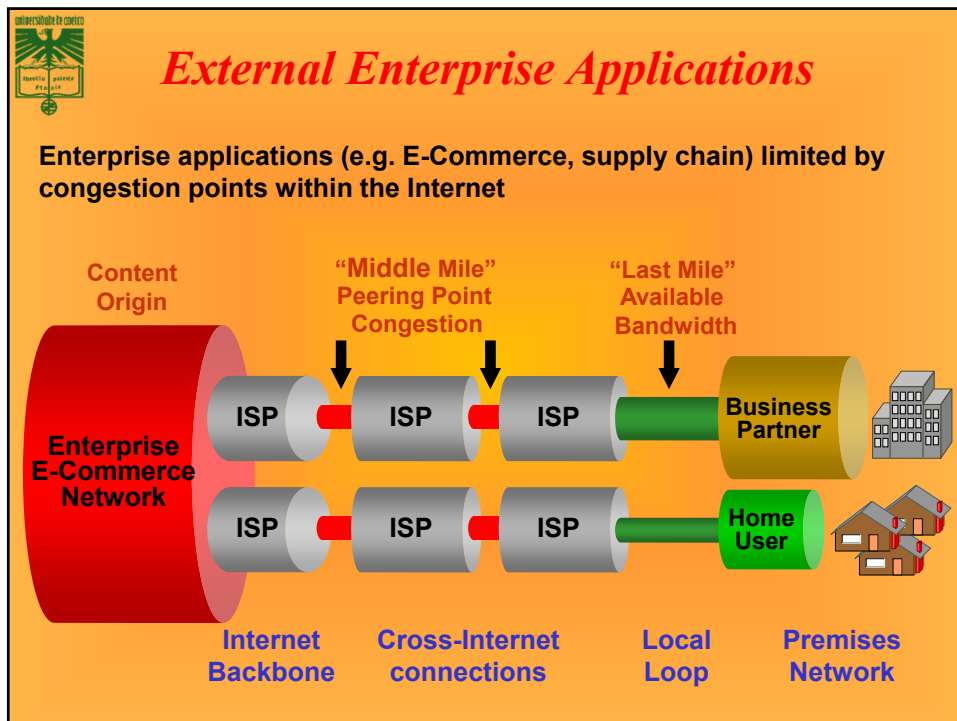

● - IP router

*This was the simpler initial concept; immediatly network applications became of concern*

40

## Flash crowd solution: CDNs..

### What is a CDN?

A network of servers delivering content on behalf of an origin site

Large-file service with

- No custom client
- No custom server
- No prepositioning
- No rehosting
- No manual provisioning

40

## CDN operation, on same scenario

41

42

## Advantages

- Better scalability
  - Higher availability
  - Improved response time from a centrally managed solution
  - Nodes constituting the distribution network are designed to be
    - Self-configuring
    - Self-managing
    - Self-diagnosing
    - Self-healing
- to ensure easy management and operational convenience.

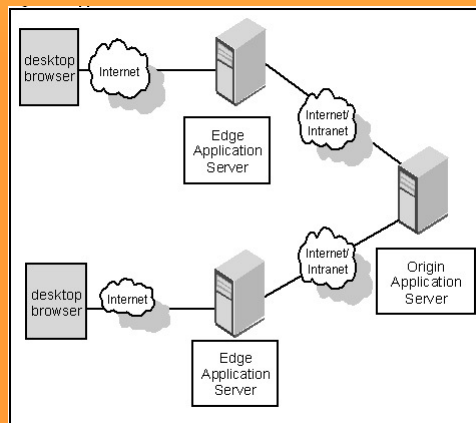

*The CDN has its own operation team, that needs to cover multiple places, even in different continents.*

42

43

## Model

**Application offload was the 1st generation unsolved challenge.**

43

## Inside a CDN

- **Servers are deployed in clusters for reliability**
  - Some may be (occasionally) offline
    - Could be due to failure
    - Also could be “suspended” (e.g., to save power or for upgrade)
- **Could be multiple clusters per location (e.g., in multiple racks, “server farms”)**
- **Server locations**
  - Well-connected points of presence (PoPs)
  - Inside of ISPs
  - IXP – internet exchange points

44

## Content distribution networks

- **Client attempts to access the main server site for an application**
- **It is redirected to one of the other sites**
- **Access a closely located site**
  - Avoid congestion on the path to the main server
  - Much shorter link paths
- **Each site caches information**
  - Avoid going to the main server to get the information/application
  - The information is pushed from the main server
- **Set of sites used to improve the performance of web-based applications collectively**
  - Content distribution infrastructure

45

46

## Challenges

- Keep consistency among the enterprise data hosted by the offloaded applications
- Share session state among edge and origin application servers
- Develop programming models consistent with industry standards such as JS, CSS...
- Distribution, configuration, and management
- Application security.

There is active research into general frameworks to be used to support distributed applications, as well as prototyping the ideas for specific application instances

46

## Load-Sharing Content

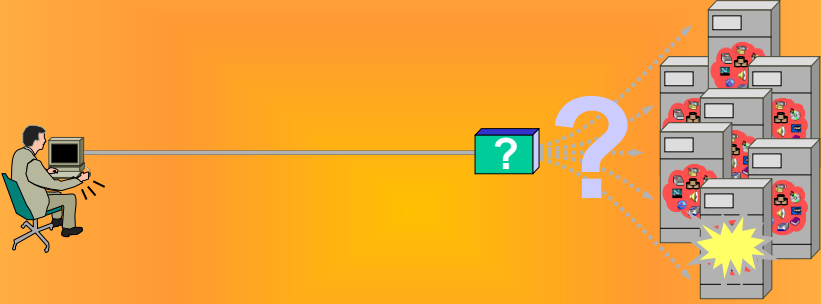

- Handle requests fairly amongst servers/sites
- Easily add servers/sites to content service
- Adjust connections based on server/site load

47

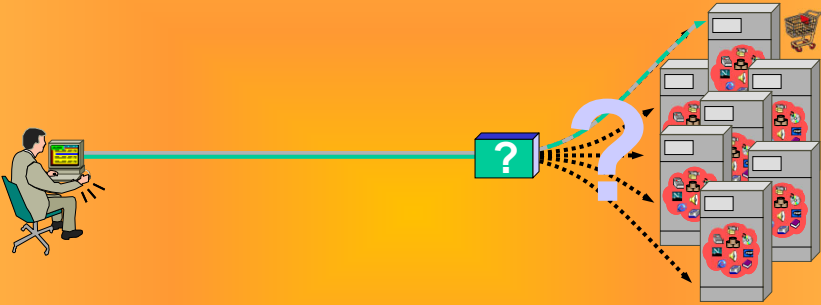

**Content Availability with multiple servers?**

- Synchronize content amongst servers/sites
- Avoid faulty servers/sites
- Faulty servers/sites includes invalid/dated content
  - Intelligent server farms in each site

48

**Persistence with multiple servers?**

- Handle applications which use 'state'
  - Need to learn client ID to satisfy state requirement
  - Need to maintain state for period of time – variable
  - Stateless programming (as much as possible)

49

50

# Outline

- Overall context
- Challenges
- Potential alternatives?
- Architecture

50

51

## With CDNs

- **Overlay network to distribute content from origin servers to users**
  - Avoids large amounts of same data repeatedly traversing potentially congested links on the Internet
  - Reduces Web server load
  - Reduces user perceived latency
  - Tries to route around congested networks
- **CDN is not a cache!**
  - Caches are used by ISPs to reduce bandwidth consumption, CDNs are used by content providers to improve quality of service to end users
  - Caches are reactive, CDNs are proactive
  - Caching proxies cater to their users (web clients) and not to content providers (web servers), CDNs cater to the content providers (web servers) and clients
  - CDNs give control over the content to the content providers, caching proxies do not

52

## CDN Components

- **Content Delivery Infrastructure:** Delivering content from producer to clients by surrogates
- **Request Routing Infrastructure:** Steering or directing content request from a client to a suitable surrogate
- **Distribution Infrastructure:** Moving or replicating content from content source (origin server, content provider) to surrogates
- **Accounting Infrastructure:** Logging and reporting of distribution and delivery activities

53

## Mapping clients to servers

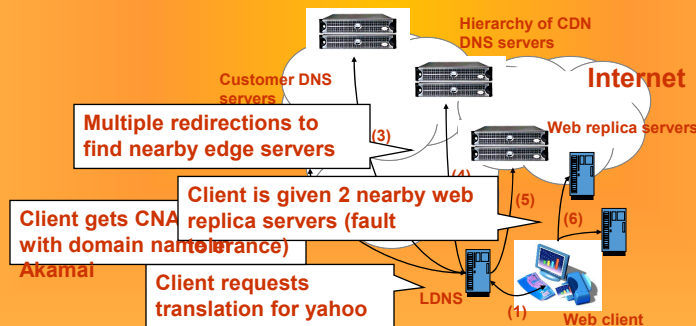

- **CDNs need a way to send clients to the “best” server**
  - The best server can change over time
  - And this depends on client location, network conditions, server load, ...
  - What existing technology can we use for this?
- **DNS-based redirection**
  - Clients request [www.foo.com](http://www.foo.com)
  - DNS server directs client to one or more IPs based on request IP
  - Use short TTL to limit the effect of caching

54

## DNS Redirection

- **Web client's request redirected to 'close' by server**
  - Client gets web site's DNS CNAME entry with domain name in CDN network
  - Hierarchy of CDN's DNS servers direct client to 2 nearby servers

55

## DNS Redirection Considerations

- **Advantages**
  - Uses existing, scalable DNS infrastructure
  - URLs can stay essentially the same
- **Limitations**
  - **DNS servers see only the DNS server IP**
    - Assumes that client and DNS server are close. Is this accurate?
  - **Content owner must give up control**
  - **Unicast addresses can limit reliability**

56

57

## What other CDN techniques are being used?

- **DNS redirection (DR)**
  - Full-site delivery
  - Partial-site delivery
- **URL rewriting**
- **Hybrid scheme**
  - URL rewriting + DNS redirection
- **Manual hyperlink selection**
- **HTTP redirection**
- **Layer 4 switching**
- **Layer 7 switching**
- **Anycast**

57

58

## Offloading a portal

- **Portal servers allow users to access content and applications from a single access point**
  - Users can create persistent, customized views of applications and content chosen from the set of applications and content by the portal administrators
- **Portal server pages are personalized**
- **Often include dynamic content**
- **Significant amount of computation required for page assembly**
  - **Application offload**

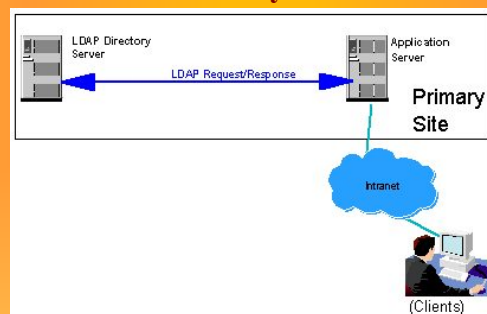

58

59

## Offloading an Enterprise directory

- **E.g. a common e-Workplace tool**
- **The employee data is often stored in a central LDAP directory**
  - **Separate web-based application providing the interface to the directory**

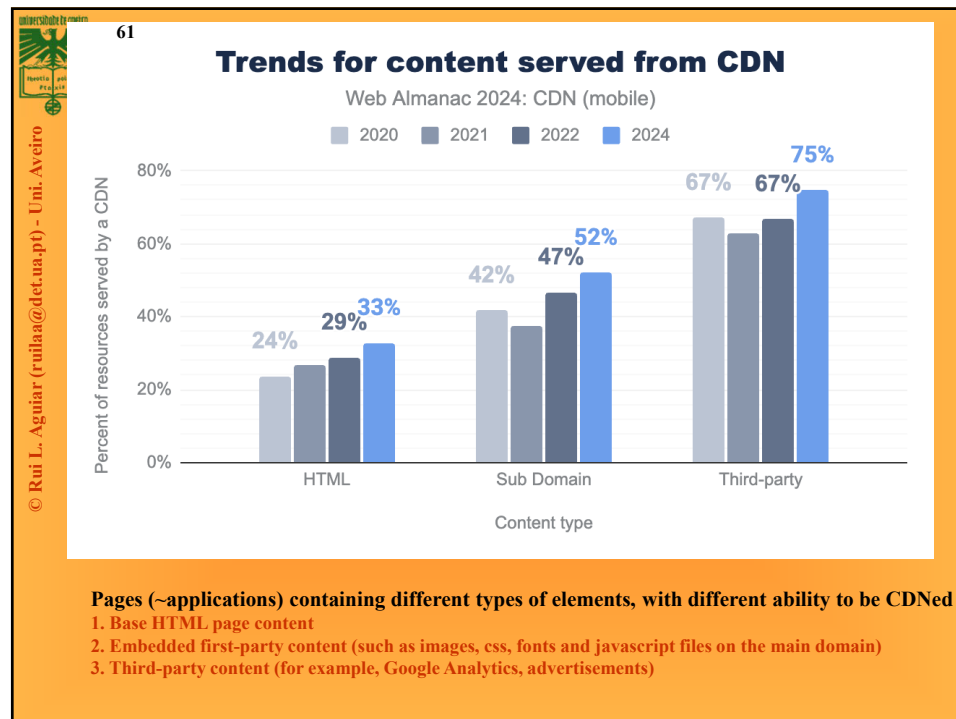

59

60

## Offloading an Enterprise directory

- **Centralized directory**
  - Convenient to manage
  - Performance for clients accessing the directory from remote sites can be poor
    - E.g. transcontinental network connections suffer from a long delay
- **Offloaded version of the application**
- **Challenge: aspects as *password update*. How to do it?**

60

61
